DrillLoop Product and Commercial Review

Q4 2026 · Status as of 27 October

Review of MVP delivery, synthetic demo results, commercial hypotheses, and next proof points. Pricing, delivery costs, customer demand, evaluator time savings, and real-world accuracy remain unvalidated.

Agenda

MVP, evidence, economics, and decisions

01	MVP status	Build
02	Synthetic results	Evidence
03	Customer segments	Demand
04	Commercial model	Hypothesis
05	Pilot priorities	Discovery
06	Decision request	Decision owner

MVP recap, evidence, and decisions

MVP Status

DEMO READY

DrillLoop turns exercise notes and event logs into source-linked finding drafts for evaluator review. The working demo covers exercise setup, evidence upload, timeline, human approval, corrective actions, and report export. Optional speech and writing models were not used in the reported benchmark.

Bottom line

No customer demand, willingness to pay, evaluator workload reduction, or real-world model accuracy has been measured. The next decision is whether to recruit pilot partners—not whether to scale a proven business.

What the benchmark shows

In one closed synthetic fixture, 8/8 log rows, 5/5 expected finding codes, and 9/9 expected evidence IDs matched. The citation check confirms that IDs were linked; it does not prove that evidence supports a claim or generalizes to new exercises.

Decision requested

Authorize discovery for a hospital-tabletop review. Interview 2–3 prospective evaluators; compare current workflow with DrillLoop on the same permitted records, then test an unfamiliar exercise if access is approved.

Current business and delivery status

Working demo; commercial assumptions remain untested.

The local demo is functional. It proposes findings with source links and leaves review decisions to authorized people.

Working MVP

Setup, uploads, linked timeline, evaluator review, action tracking, and PDF report export work in the demo.

Synthetic benchmark

One fictional case: 8/8 event rows, 5/5 findings, and 9/9 expected source IDs matched.

Buyer hypothesis

Hospital-preparedness evaluators are the proposed first users; approver, budget owner, and purchasing route are unknown.

Key risk

Security controls and performance on unfamiliar exercises need review; use synthetic or explicitly approved records.

Priorities for the next proof point

Discovery and a paired review should answer three practical questions:

Can hospital evaluators verify source evidence efficiently?

Compare current practice and DrillLoop on the same permitted records. Check whether citations support each finding and actions have owners and closure proof; measure time and corrections without assuming savings.

Interview users

Interview 2–3 hospital-preparedness evaluators; observe the current review with permission.

Measure review workload

Time evidence lookup and report drafting; count reviewer edits and citation corrections.

Verify action closure

Check owners, due dates, completion tests, and reviewer-confirmed closure evidence.

Value hypotheses to test

No savings or willingness to pay have been measured.

A proposed review should test source traceability, evaluator corrections, and action follow-through in an existing exercise workflow.

Existing platforms already offer after-action reports and follow-up tasks. DrillLoop's positioning hypothesis is the connected trail from claim to source, reviewer decision, and verified closure—not report generation alone.

Evidence trace

Open the source row, note line, or transcript segment behind a proposed claim.

Human review

Keep each draft pending until an authorized evaluator approves or rejects it.

Verified follow-through

Track the owner and due date; close only after a reviewer checks completion proof.

What is delivered—and what remains unproven

Delivered in the MVP

The app sets up exercises and accepts evaluator notes, event logs, and readable PDFs. It places recorded events on a timeline, flags conflicting times, and attaches each draft finding to its source.

Reviewers can accept or reject drafts, assign owners and due dates, specify how completion will be checked, record closure proof, and export a report. SQLite supports the local demo; PostgreSQL is available in Compose for deployment experiments.

Optional speech-to-text and text-drafting models can run locally. Neither was used in the reported benchmark.

Still unproven

No customer interviews, paid pilots, manual timing baseline, reviewer correction study, real-audio accuracy, or local-model quality results are available.

The perfect fixture scores reflect labels built for one fictional scenario. They do not establish general performance. Enterprise login, role-based access, and buyer demand also need validation.

Target markets are hypotheses, not customers

Start with hospital-preparedness evaluators reviewing tabletop exercises. Municipal teams, airports, civil defense and disaster agencies, training providers, defense-support teams, and critical infrastructure operators are later hypotheses. No customer list, sales pipeline, market-size estimate, or willingness-to-pay evidence is available.

Synthetic benchmark: what actually matched

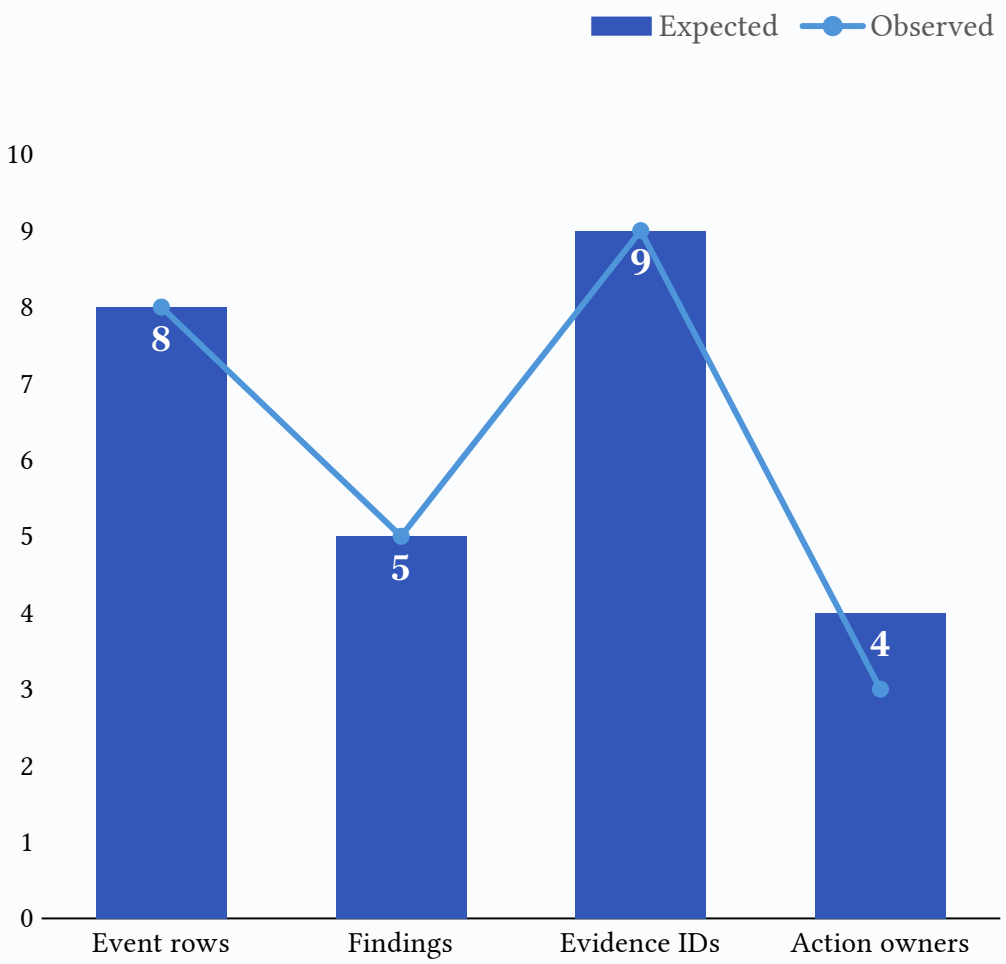

All perfect matches come from one closed fictional exercise fixture.

The test checks whether expected rows, finding codes, and evidence links are present. A linked record ID does not prove that the source supports the claim.

One timing disagreement was flagged and one untimed note stayed unplaced. No human evaluators, real audio, or unseen exercise records were tested.

Metric	Result	What it shows	Boundary
Log rows	8 / 8	Expected rows found	One fixture
Findings	5 / 5	Expected codes found	One fixture
Citations	9 / 9	Expected IDs linked	ID only
Extra codes	0 / 5	No extra labels	Closed set
Uncited drafts	0 / 5	Each draft linked	ID presence
Timing	1 + 1	Conflict flagged; note unplaced	One fixture
Action fields	31 / 32	One owner blank	Synthetic data
Rule time	4.61 / 9.13 ms	Median / 95th percentile	12 local calls
Memory	78.2 MB	App and test tools	No model

Synthetic fixture counts

Event rows

8 of 8 expected log rows were found.

Finding codes

All 5 expected finding codes were proposed.

Action owners

3 of 4 have owners; one is intentionally blank.

Commercial model to validate

Evidence to collect

Who prepares, approves, and pays?

What setup, security, hosting, and support are required?

What does the current workflow take, and where are corrections made?

TBD

No customer demand, revenue, or delivery-cost evidence.

Pilot fee

Per-exercise pilot fee.

Annual subscriptions, private deployment, templates, and support are later hypotheses. Confirm buyer, purchasing route, and delivery needs before modeling economics.

Proposed stages: discover, compare, then decide

Discovery

Learn the workflow

Interview 2–3 prospective hospital evaluators; observe current review with permission and identify approver and budget roles.

Paired review

Compare on the same records

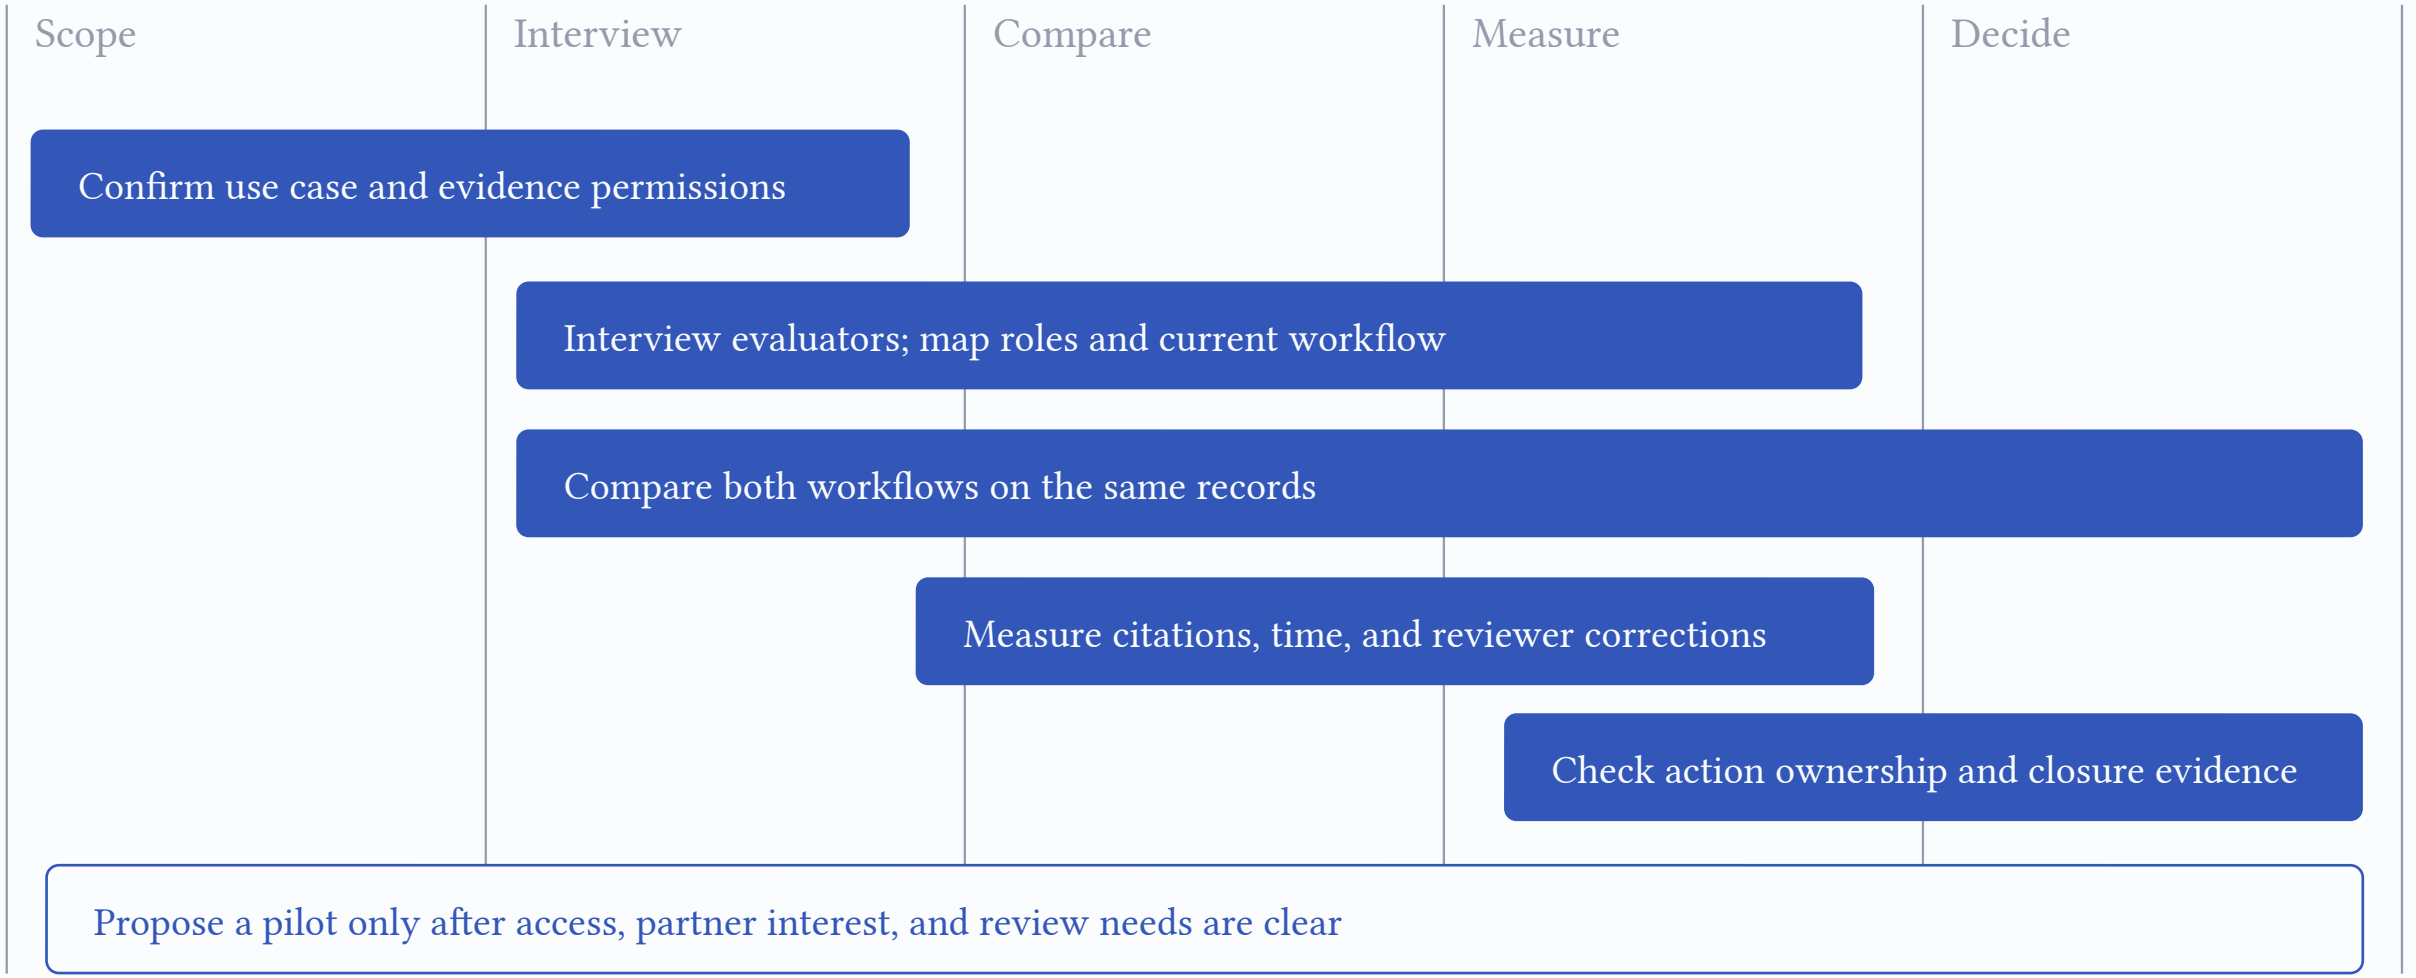

With permission, compare current practice and DrillLoop; measure time, corrections, citation support, and action fields.

Next decision

Test generalization

If approved records are available, test evaluator-labeled evidence from an unfamiliar exercise and agree next thresholds with a partner.

Illustrative discovery and review sequence

Decision requested

Authorize discovery and a paired-review design for the hospital tabletop use case.

Interview 2–3 prospective evaluators and observe an existing review only with permission; confirm approver, budget owner, and evidence controls.

Compare current practice and DrillLoop on the same permitted records, then return with findings before proposing a pilot or success thresholds.
